## LCS Overview

The Longest Common Subsequence (LCS) problem is finding the longest subsequence present in given two sequences in the same order.
This algorithm is used in numerous fields such as bioinformatic, data mining, social networks, computer security, Git Merging etc.

Eg:

Longest common subsequence is: B A C B D
So the longest length $=5$

## DP Approach

The dynamic programming is a classical approach for solving the LCS problem.
It is based on the filling of a score matrix through a scoring mechanism(a recursive formula).

$$
c[i, j]= \begin{cases}0 & \text { if } i \text { or } j=0 \\ c[i-1, j-1]+1 & \text { if } x_{i}=y_{i} \\ \max (c[i, j-1], c[i-1, j]) & \text { if } x_{i} \neq y_{i}\end{cases}
$$

The scoring table is filled row by row using the scoring function.
The highest calculated score is the length of the LCS and the subsequence can be found by tracing back the table.

University at Buffalo The State University of New York

## DP Approach

Time and Space Complexity: $\mathrm{O}(\mathrm{mxn})$, where m and n are length of the 2 strings.

Data dependency in the score matrix

University at Buffalo The State University of New York

## Anti-Diagonal Parallel Approach

Computing the table in diagonal major order, each element of the diagonal can be computed independently given that the previous diagonals are already computed.

|  | j | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| i |  | y | A | C | B | C | B | A | B |
| 0 | x | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| 1 | B | 0 |  |  |  |  |  |  |  |
| 2 | A | 0 |  |  |  |  |  |  |  |
| 3 | B | 0 |  |  |  |  |  |  |  |
| 4 | C | 0 |  |  |  |  |  |  |  |
| 5 | A | 0 |  |  |  |  |  |  |  |
| 6 | C | 0 |  |  |  |  |  |  |  |
| 7 | B | 0 |  |  |  |  |  |  |  |

The value is rank of the process which is assigned to compute the value. (4 processes)

## Anti-Diagonal Parallel Approach

University at Buffalo The State University of New York

## Anti-Diagonal Parallel Approach

Every diagonal is computed by the N processes, with each process working on a block of data.

- The first one is to broadcast the one sequence to all nodes.
- The second part is to scatter another sequence to all nodes.
- The last one is to send/receive the completed part to other nodes. Once the data is scattered to all nodes, each node will just calculate a piece of the data instead of running the entire data in every node.

University at Buffalo The State University of New York

## Adjacent blocks

- Evaluating an entry at the boundary between two processes depend on entries of adjacent processes in previous diagonal.
- Solution: When a process computes its own block of diagonals, it receives the last element computed by the previous process and first element of following process.

Eg: Process 1 sends 1st entry of its own block to process 0 and the last element to process 2.

## Result - Sequential

| Input size |  |
| ---: | ---: |
| time (ms) |  |
| 8 | 0.004053 |

## Observations

1. As a result of parallelization, computations are faster for large number of data.
2. As the number of processors increase, the communication overhead between the processors increase which results in longer computation time.
3. Hence selecting the optimal number of processors is critical for good computation results.
