OS Design Approaches

Operating System Design and Implementation

• Start by defining goals and specifications
• Affected by choice of hardware, type of system
  - Batch, time shared, single user, multi user, distributed
• User goals and System goals
  - User goals - operating system should be convenient to use, easy to learn, reliable, safe, and fast
  - System goals - operating system should be easy to design, implement, and maintain, as well as flexible, reliable, error-free, and efficient
• No unique solution for defining the requirements of an OS
  → Large variety of solutions
  → Large variety of OS
Operating System Design and Implementation (Cont.)

• Important principle: to separate policies and mechanisms
  
  **Policy:** What will be done?
  **Mechanism:** How to do something?

• Eg. to ensure CPU protection
  - Use Timer construct (mechanism)
  - How long to set the timer (policy)

• The separation of policy from mechanism allows maximum **flexibility** if policy decisions are to be changed later

OS Design Approaches

• Simple Structure (Monolithic)
• Layered Approach
• Microkernels
• Modules
Simple Structure

- Monolithic
- No well defined structure
- Start as small, simple, limited systems, and then grow
- No Layers, not divided into modules

Example: MS-DOS

- Initially written to provide the most functionality in the least space
- Started small and grew beyond its original scope
- Levels not well separated: programs could access I/O devices directly
- Excuse: the hardware of that time was limited (no dual user/kernel mode)
Layered Approach

- **Monolithic operating systems**
  - no one had experience in building truly large software systems
  - the problems caused by mutual dependence and interaction were grossly underestimated
  - such lack of structure became unsustainable as O/S grew

- **Enter hierarchical layers and information abstraction**
  - each layer is implemented exclusively using operations provided by lower layers
  - it does not need to know how they are implemented
  - hence, lower layers hide the existence of certain data structures, private operations and hardware from upper layers

---

Simple Layered Approach

- **The original UNIX**
  - enormous amount of functionality crammed into the kernel - everything below system call interface
  - "The Big Mess": a collection of procedures that can call any of the other procedures whenever they need to
  - no encapsulation, total visibility across the system
  - very minimal layering made of thick, monolithic layers

Layered Approach

- The operating system is divided into a number of layers (levels), each built on top of lower layers.
  - The bottom layer (layer 0), is the hardware;
  - The highest (layer N) is the user interface.

- With modularity, layers are selected such that each uses functions (operations) and services of only lower-level layers
  - GLUnix, Multics, VAX/VMS

Layered Approach

- Layers can be debugged and replaced independently without bothering the other layers above and below

- famous example of strictly layered architecture: the TCP/IP networking stack

### Major difficulty with layering

- . . . appropriately defining the various layers!
- Layering is only possible if all function dependencies can be sorted out into a Directed Acyclic Graph (DAG)
- However there might be conflicts in the form of circular dependencies (“cycles”)

![Circular dependency on top of a DAG](image)
Layered Approach

- Circular dependencies in an O/S organization
  - example: disk driver routines vs. CPU scheduler routines
    - the device driver for the backing store (disk space used by virtual memory) may need to wait for I/O, thus invoke the CPU-scheduling layer
    - the CPU scheduler may need the backing store driver for swapping in and out parts of the table of active processes

- Other difficulty: efficiency
  - the more layers, the more indirections from function to function and the bigger the overhead in function calls
  - backlash against strict layering: return to fewer layers with more functionality

Microkernel System Structure

- The microkernel approach
  - a microkernel is a reduced operating system core that contains only essential O/S functions
  - the idea is to minimize the kernel by moving up as much functionality as possible from the kernel into user space
  - many services traditionally included in the O/S are now external subsystems running as user processes
    - device drivers
    - file systems
    - virtual memory manager
    - windowing system
    - security services, etc.

- Examples: QNX, Tru64 UNIX, Mach (CMU), Windows NT
**Microkernel System Structure**

- **Benefits of the microkernel approach**
  - **extensibility** — it is easier to extend a microkernel-based O/S as new services are added in user space, not in the kernel
  - **portability** — it is easier to port to a new CPU, as changes are needed only in the microkernel, not in the other services
  - **reliability & security** — much less code is running in kernel mode; failures in user-space services don’t affect kernel space

- **Detriments of the microkernel approach**
  - again, performance overhead due to communication from user space to kernel space
  - not always realistic: some functions (I/O) must remain in kernel space, forcing a separation between “policy” and “mechanism”
Modular Approach

- The modular approach
  - many modern operating systems implement kernel modules
  - this is similar to the object-oriented approach:
    - each core component is separate
    - each talks to the others over known interfaces
    - each is loadable as needed within the kernel
  - overall, modules are similar to layers but with more flexibility
  - modules are also similar to the microkernel approach, except they are inside the kernel and don’t need message passing

---

Modular Approach

- Modules are used in Solaris, Linux and Mac OS X

The Solaris loadable modules

Mac OS X Structure - Hybrid

- **BSD**: provides support for command line interface, networking, file system, POSIX API and threads
- **Mach**: memory management, RPC, IPC, message passing

Major OS Components
Major OS Components

- Processes
- Memory management
- CPU Scheduling
- I/O Management

Processes

A process is the activity of executing a program

Pasta for six
- boil 1 quart salty water
- stir in the pasta
- cook on medium until “al dente”
- serve
Processes

- It can be interrupted to let the CPU execute a higher-priority process.

First aid:
- Get the first aid kit
- Check pulse
- Clean wound with alcohol
- Apply band aid

CPU (changes hat to "doctor")

Program

- boil 1 quart salty water
- stir in the pasta
- cook on medium until "al dente"
- serve

CPU (back to "chef")

hmm... now where was I?

Program
Processes

- **Multitasking** gives the illusion of parallel processing (independent virtual program counters) on one CPU

(a) Multitasking from the CPU’s viewpoint

(b) Multitasking from the processes’ viewpoint = 4 virtual program counters

*Pseudoparallelism in multitasking*

---

Processes

- **Timesharing** is a logical extension in which CPU switches jobs so frequently that users can interact with each job while it is running, creating interactive computing
  - **Response time** should be < 1 second
  - Each user has at least one program loaded in memory and executing ⇒ **process**
Processes

- Operating System Responsibilities:

The O/S is responsible for managing processes:
- the O/S creates & deletes processes
- the O/S suspends & resumes processes
- the O/S schedules processes
- the O/S provides mechanisms for process synchronization
- the O/S provides mechanisms for interprocess communication
- the O/S provides mechanisms for deadlock handling

Memory Management

- Operating System Responsibilities:

The O/S is responsible for an efficient and orderly control of storage allocation:
- ensures process isolation: it keeps track of which parts of memory are currently being used and by whom
- allocates and deallocates memory space as needed: it decides which processes to load or swap out
- regulates how different processes and users can sometimes share the same portions of memory
- transfers data between main memory and disk and ensures long-term storage
Memory Management

- **Main memory**
  - large array of words or bytes, each with its own address
  - repository of quickly accessible data shared by the CPU and I/O devices
  - volatile storage that loses its contents in case of system failure

The storage hierarchy

Performance of Various Levels of Storage

- Movement between levels of storage hierarchy can be explicit or implicit

Caching

- Important principle, performed at many levels in a computer (in hardware, operating system, software)
- Information in use copied from slower to faster storage temporarily
- Faster storage (cache) checked first to determine if information is there
  - If it is, information used directly from the cache (fast)
  - If not, data copied to cache and used there
- If cache is smaller than storage being cached
  - Cache management - important design problem
  - Cache size and replacement policy

Migration of Integer A from Disk to Register

- Multitasking environments must be careful to use most recent value, not matter where it is stored in the storage hierarchy

- Multiprocessor environment must provide cache coherency in hardware such that all CPUs have the most recent value in their cache
- Distributed environment situation even more complex
  - Several copies of a datum can exist
CPU Scheduling

- **Operating System Responsibilities:**

  The O/S is responsible for efficiently using the CPU and providing the user with short response times.

  - decides which available processes in memory are to be executed by the processor
  - decides what process is executed when and for how long, also reacting to external events such as I/O interrupts
  - relies on a scheduling algorithm that attempts to optimize CPU utilization, throughput, latency, and/or response time, depending on the system requirements

OS Scheduling

- **Long-term scheduling**
  - the decision to add a program to the pool of processes to be executed (job scheduling)

- **Medium-term scheduling**
  - the decision to add to the number of processes that are partially or fully in main memory ("swapping")

- **Short-term scheduling = CPU scheduling**
  - the decision as to which available processes in memory are to be executed by the processor ("dispatching")

- **I/O scheduling**
  - the decision to handle a process's pending I/O request
I/O Management

- **Operating System Responsibilities:**

  The O/S is responsible for controlling access to all the I/O devices
  - hides the peculiarities of specific hardware devices from the user
  - issues the low-level commands to the devices, catches interrupts and handles errors
  - relies on software modules called “device drivers”
  - provides a device-independent API to the user programs, which includes buffering

Layers of the I/O subsystem
Two I/O Methods

- After I/O starts, control returns to user program only upon I/O completion → **synchronous**
  - Wait instruction idles the CPU until the next interrupt
  - Wait loop (contention for memory access).
  - At most one I/O request is outstanding at a time, no simultaneous I/O processing.

- After I/O starts, control returns to user program without waiting for I/O completion → **asynchronous**
  - *System call* - request to the operating system to allow user to wait for I/O completion.
  - *Device-status table* contains entry for each I/O device
