## Fast Methods with Sieve

#### Matthew G Knepley

Mathematics and Computer Science Division Argonne National Laboratory

August 12, 2008 Workshop on Scientific Computing Simula Research, Oslo, Norway

A (10) A (10)

- Can we establish good interfaces for all levels of the hierarchy?
- Do we need language extensions for more sophisticated problems?
- What information is required from each component?
- Is inter-language programming effective?
- Can we develop a general framework for boundary conditions?

# Outline

## Quadtree Implementation

- We use binary scheme to label cells (or vertices)
- Relevant relations can be determined implicitly
  - cone()
  - neighbors
  - parent
  - interaction list
- When vertices are not used, we can directly connect cells
  - cone () becomes neighbor method

#### Tree Interface

- locateBlob(blob)
  - Locate point in the tree
- fillNeighbors()
  - Compute the neighbor section
- findInteractionList()
  - Compute the interaction list cell section, allocate value section
- fillInteractionList(level)
  - Compute the interaction list value section
- fill(blobs)
  - Compute the blob section
- dump()
  - Produces a verifiable repesentation of the tree

A .

FMM requires data over the Quadtree distributed by:

- box
  - Box centers, Neighbors
- box + neighbors
  - Blobs
- box + interaction list
  - Interaction list cells and values
  - Multipole and local coefficients

Notice this is multiscale since data is divided at each level

# Outline

- Spatial Decomposition
- 2 Data Decomposition
- 3 Serial Implementation
- 4 Parallel Spatial Decomposition
- 5 Parallel Performance

#### **Evaluator Interface**

#### • initializeExpansions(tree, blobInfo)

- · Generate multipole expansions on the lowest level
- Requires loop over cells
- *O*(*p*)
- upwardSweep(tree)
  - Translate multipole expansions to intermediate levels
  - Requires loop over cells and children (support)
  - O(p<sup>2</sup>)
- downwardSweep(tree)
  - Convert multipole to local expansions and translate local expansions on intermediate levels
  - Requires loop over cells and parent (cone)
  - $O(p^2)$

#### **Evaluator Interface**

#### • evaluateBlobs(tree, blobInfo)

- Evaluate direct and local field interactions on lowest level
- Requires loop over cells and neighbors (in section)
- *O*(*p*<sup>2</sup>)
- evaluate(tree, blobs, blobInfo)
  - Calculate the complete interaction (multipole + direct)

#### Kernel Interface

Method	Description
P2M(t)	Multipole expansion coefficients
L2P(t)	Local expansion coefficients
M2M(t)	Multipole-to-multipole translation
M2L(t)	Multipole-to-local translation
L2L(t)	Local-to-local translation
evaluate(blobs)	Direct interaction

- Evaluator is templated over Kernel
- There are alternative kernel-independent methods
  - kifmm3d

## Parallel Tree Implementation

- Divide tree into a root and local trees
- Distribute local trees among processes
- Provide communication pattern for local sections (overlap)
  - Both neighbor and interaction list overlaps
  - Sieve generates MPI from high level description

#### Parallel Tree Implementation How should we distribute trees?

- Multiple local trees per process allows good load balance
- Partition weighted graph
  - Minimize load imbalance and communication
  - Computation estimate:

Leaf  $N_i p$  (P2M) +  $n_l p^2$  (M2L) +  $N_i p$  (L2P) +  $3^d N_i^2$  (P2P) Interior  $n_c p^2$  (M2M) +  $n_l p^2$  (M2L) +  $n_c p^2$  (L2L)

• Communication estimate:

Diagonal  $n_c(L-k-1)$ Lateral  $2^{d} \frac{2^{m(L-k-1)}-1}{2^m-1}$  for incidence dimesion *m* 

Leverage existing work on graph partitioning

• ParMetis

#### Parallel Tree Implementation Why should a good partition exist?

Shang-hua Teng, Provably good partitioning and load balancing algorithms for parallel adaptive N-body simulation, SIAM J. Sci. Comput., **19**(2), 1998.

- Good partitions exist for non-uniform distributions
   2D O (√n(log n)<sup>3/2</sup>) edgecut
   3D O (n<sup>2/3</sup>(log n)<sup>4/3</sup>) edgecut
- As scalable as regular grids
- As efficient as uniform distributions
- ParMetis will find a nearly optimal partition

#### Parallel Tree Implementation Will ParMetis find it?

George Karypis and Vipin Kumar, Analysis of Multilevel Graph Partitioning, Supercomputing, 1995.

- Good partitions exist for non-uniform distributions 2D  $C_i = 1.24^i C_0$  for random matching 3D  $C_i = 1.21^i C_0$ ?? for random matching
- 3D proof needs assurance that averge degree does not increase
- Efficient in practice

# Parallel Tree Implementation

# Parallel Tree Interface

- fillNeighbors()
  - Compute neighbor overlap, and send neighbors
- findInteractionList()
  - Compute the interaction list overlap
- fillInteractionList(level)
  - Complete and copy into local interaction sections
- fill(blobs)
  - Now must scatter blobs to local trees
  - Uses scatterBlobs() and gatherBlobs()

# Parallel Data Movement

#### Complete neighbor section

#### Opward sweep

- Upward sweep on local trees
- Ø Gather to root tree
- Opward sweep on root tree
- Omplete interaction list section
- Oownward sweep
  - Downward sweep on root tree
  - Scatter to local trees
  - Ownward sweep on local trees

## Parallel Evaluator Interface

- initializeExpansions(local trees, blobInfo)
  - Evaluate each local tree
- upwardSweep(local trees, partition, root tree)
  - Evaluate each local tree and then gather to root tree
- downwardSweep(local trees, partition, root tree)
  - Scatter from root tree and then evaluate each local tree
- evaluateBlobs(local trees, blobInfo)
  - Evaluate on all local trees
- evaluate(tree, blobs, blobInfo)
  - Identical

## **Recursive Parallel**

- For large problems, a single root can be a bottleneck
- We can recursively assign roots to subtrees
  - Bandwidth to root is controlled
  - What about utilization?
- Root computation is similar to MG coarse solve
